COMPETITIVE SHRUBS

- **Extensive shrub monolayers can be caused by disturbance**

(Royo and Carson, 2006)

- **Specific competitive shrubs traits: fast vegetative growth, protection from fire/browsing and relatively long life spans**

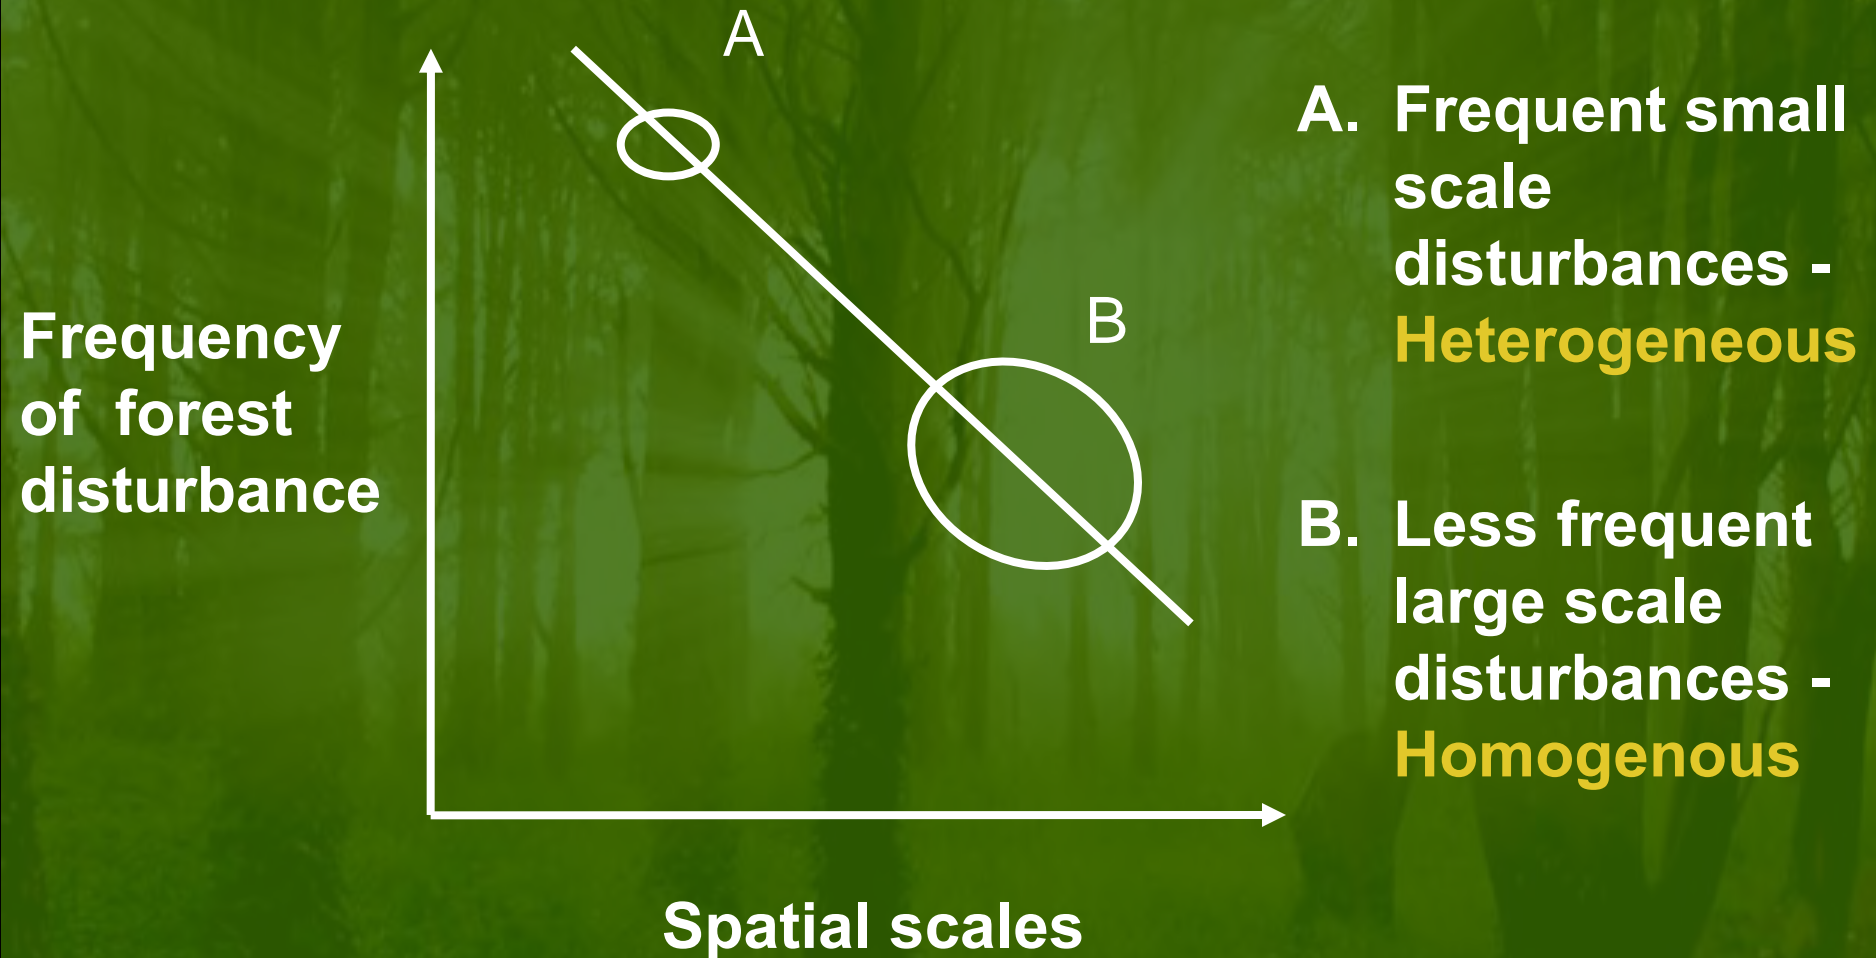

(Young and Peffer, 2010)

SOUTHERN MIXEDWOODS

- **Bf-Yb climax stands are typically an uneven age structure** (*Prévost et al. 2003*)
- These stands are therefore inherently **HETEROGENEOUS**
- Vulnerable to **competitive shrubs?**

THE IMPORTANCE OF SPATIAL SCALES

FOREST STRUCTURE

- **Tree density**
- **Tree height**
- **Canopy cover**
- **Tree DBH**
- **Tree spacing**
- **Tree species**

(McElhinny et al. 2005)

LANDSCAPE STRUCTURE

- **Patch size**
- **Amount of habitat**
- **Number of habitat patches**
- **Habitat interpatch distance**
- **Patch size distribution**
- **Edge to interior ratio**

(Goodwin and Fahrig, 2002)

LANDSCAPE SPATIAL STRUCTURE

Amount of habitat

8 % ←

→ 32 %

Number of habitat patches

two ←

→ many

Habitat interpatch distance

near ←

→ far

(Goodwin and Fahrig, 2002)

Introduction

GENERAL HYPOTHESIS

The **spatio-temporal organisation of canopy openings** will influence tree and shrub regeneration

Cumulated effects of natural and anthropogenic **disturbance** at the landscape scale results in a **build-up of shrub** populations

(Royo and Carson, 2006)

SPECIFIC HYPOTHESIS

- (1) Heterogeneous landscapes would contain a **greater density** of competitive clonal shrubs, because of the greater concentration of gap openings
- (2) Large shrub populations would **reduce the growth** of tree species in heterogeneous landscapes

SAMPLING

Response variables:

- density
- growth
- species {YB, WS, SM, RM, WB, MM, BF, WC}

Explanatory variables:

- landscape heterogeneity
- gap size
- gap position
- competition
- browsing

Statistics:

- Poisson mixed regression (density)
- AIC model selection (growth)
- ANOVA mixed model (growth)
- Random factor site nested in landscape
- $P(f) < 0.05$

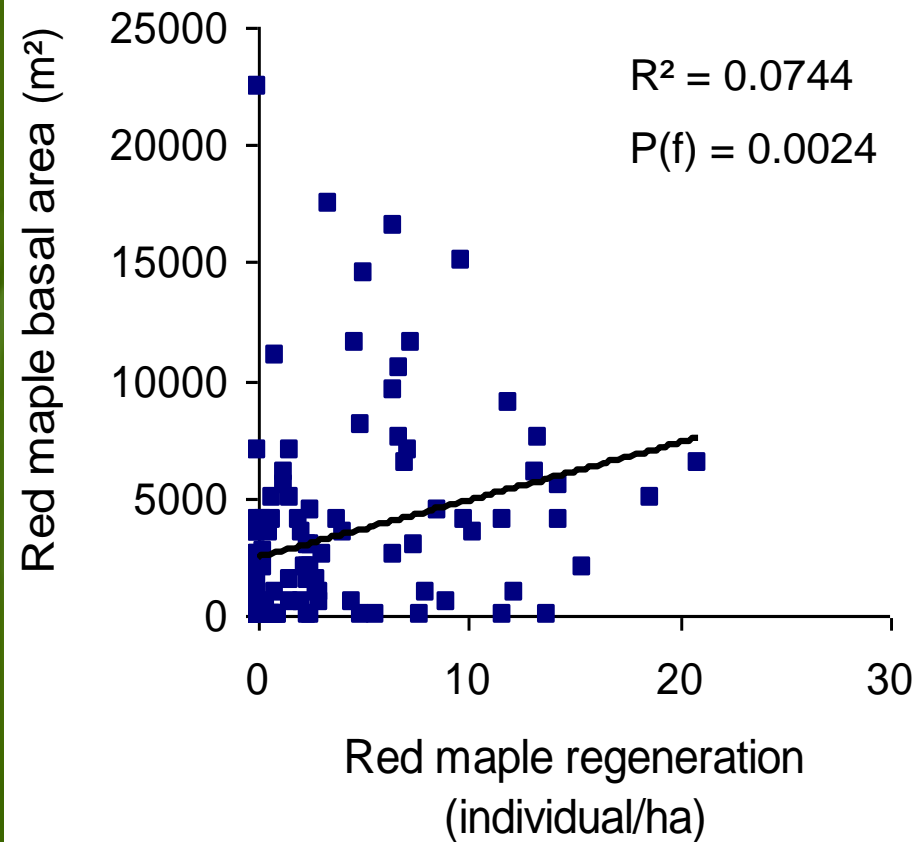

LANDSCAPE LEVEL CONTROLS

Criteria selected via GIS:

- **Composition** {> 50% Yb/Bf/Wb}
- **Age** {> 70 years}
- **Disturbance** {partial cutting, diameter limit, spruce budworm}
- **Drainage** {medium, classes 2 & 3}
- **Till deposits** {1A/1AR > 0.5m till}

Conclusion

IMPLICATIONS

Forest management:

- Inclusion of landscape heterogeneity and landscape level factors into forestry decisions

Forest ecology:

- Landscape level factors influence local phenomena

R CODE FOR AIC MODEL

```
library(AICcmodavg)
library(lme4)
data1 <- read.table("fun", header = TRUE)
Cand.models <- list( )
Cand.models[[1]] <- glmer(specify variable ~
  specify factors + (1 | random factor), data =
  data1, REML = FALSE)
Cand.models[[2]] <- specify variable ~ specify
  factors2 + (1 | random factor), data = data1,
  REML = FALSE)
Modnames <- c("specify factors", "specify
  factors2")
aic.table.1 <- aictab(cand.set = Cand.models,
  modnames = Modnames)
aic.table.1
```

SUMMARY

Potential processes involved in density response to landscape heterogeneity:

- **Possibility that large shrub populations impede tree ESTABLISHMENT...**
- **Species specific response to disturbance: the importance of FUNCTIONAL TRAITS**
- **METAPOPULATION DYNAMICS: the local extinction of seed trees and shrubs**

DISCRIMINANT ANALYSIS – GAP TREE COMPOSITION AND LANDSCAPE HETEROGENEITY

REGENERATION GROWTH AIC MODEL SELECTION

Suggested Models seedlings all species

	Delta AICc	AICc Wt	Cum Wt
1 Competition + Gap size	0	0.67	0.67
2 Competition	1.85	0.27	0.94
3 Landscape heterogeneity + Competition	4.93	0.06	0.99
4 Landscape heterogeneity + Gap size + Gap position + Competition + Browsing	9.16	0.01	1
5 Gap size	83.79	0	1
